

Microflows

Mendix Microflows execute primarily on the server.

They are commonly used for business logic, database operations, integrations and server-side processing

Nanoflows

Mendix Nanoflows can execute on the client.

Nanoflows are especially useful for mobile and offline applications.

They can perform logic locally and can interact with device capabilities.

PWA

Mendix PWA applications can support offline scenarios.

Data can be synchronized between the local device database and the server when connectivity is available.

Rag Intro

Retrieval Augmented Generation, or RAG, combines information retrieval with a language model. Relevant documents are retrieved first and supplied to the language model as context.

Self Rag

Self-RAG evaluates its own retrieved context and generated response.

If the answer is insufficient, the system can perform another retrieval or generation step.

Corrective Rag

Corrective RAG evaluates whether retrieved documents are relevant.

If retrieval quality is poor, the system can correct the retrieval process, for example by rewriting the query or using another source.

Fusion rag

Fusion RAG generates multiple query variations for the same question.

Each query retrieves documents independently. The results are then combined and reranked before the final answer is generated.
